The properties of FE materials are sensitive to atomic displacements and strain, so it is essential to start our calculation with accurate structural parameters. The lattice constants and Wyckoff positions obtained from our calculations are summarized in the Tables I and II, with experimental results provided for reference. Our structure parameters are very close to the experimental results.

To investigate the magnetic structures of  $Mn_2FeWO_6$  and  $Mn_3WO_6$ , four different types of unit cell are considered in the calculation. We adopt a notation like "udu" to describe the possible spin structure, where "u" is spin-up, "d" is spin-down, and the spins are given on atom  $\beta$ ,  $\delta$  and  $\gamma$ , in that order. The four possible states (not counting those that are trivially related by a global spin reversal) are uuu, uud, udu, and udd. The energy of each fully-relaxed magnetic structure is listed in Table III. Of those, the most stable state for both  $Mn_2FeWO_6$  and  $Mn_3WO_6$  is udu. However, for  $Mn_3WO_6$ , the energy difference between the uud and udu states is tiny, so we considered the polarization reversal for both magnetic states.

The magnetic ground states of  $Mn_2FeWO_6$  and  $Mn_3WO_6$  can be understood by analyzing the super-exchange interactions between  $A_1$ ,  $A_2$  and B cations (also shown as  $\beta$ ,  $\gamma$  and  $\delta$  cations). The magnetic moments are coupled through the oxygen octahedra, and there are three independent coupling constants. The moments on  $A_2$  and B sites are coupled through face-sharing and corner-sharing oxygen octahedra with strength  $J_{A_2B}$ ; the  $A_1$  and B moments are coupled through edge-sharing octahedra with strength  $J_{A_1B}$ ; and the  $A_1$  and  $A_2$  moments are coupled through corner-sharing octahedra with strength  $J_{A_1A_2}$ . Then the magnetic energy  $E_{mag}$  can be written as

$$E_{\text{mag}} = J_{A_1 B} \hat{S}_{A_1} \cdot \hat{S}_B + J_{A_2 B} \hat{S}_{A_2} \cdot \hat{S}_B + J_{A_1 A_2} \hat{S}_{A_1} \cdot \hat{S}_{A_2}, \tag{1}$$

where  $\hat{S}$  represent the spin on each site. Substituting the energy of different magnetic orderings in Table III into Eq.(1), we find that the coupling constants are all positive. This result implies that the three magnetic moments all favor AFM coupling. However, it is impossible to make three collinear spins couple antiferromagnetically, and this frustration implies that one pair must be ferromagnetically coupled.

In Table IV we list the relative spin orientations of the magnetic ions. Since the face-sharing coupling  $J_{A_2B}$  is the strongest, it is not surprising that the  $A_2$  and B moments couple antiferromagnetically; the competition between  $J_{A_1B}$  and  $J_{A_1A_2}$  then determines the magnetic ground state. In Mn<sub>3</sub>WO<sub>6</sub>, these two couplings are comparable, so the energy difference between the uud and udu states is tiny. In the case of Mn<sub>2</sub>FeWO<sub>6</sub>, the magnetic moment on the B cation is smaller, so the coupling  $J_{A_1B}$  is weaker than  $J_{A_1A_2}$ . Therefore, the lowest-energy state is udu.

For the ordered-LNO materials the two A cations are inequivalent, and one of them is already closer to the oxygen plane in the ground state ( $\xi_{1S} \neq \xi_{2S}$ ). Therefore it is energetically favorable for this particular A cation to migrate first in the reversal path, which causes either the B or B' cation to be sandwiched between two A cations in the midpoint structure. If  $\xi_{1S} > \xi_{2S}$ , the sandwiched cation is B; otherwise it is B'. By calculating the energy difference  $\Delta E = E_B - E_{B'}$  between the B and B' sandwiched midpoint structures, we find that the cations that are sandwiched in the midpoint structures are Zr for Li<sub>2</sub>ZrTeO<sub>6</sub>, Hf for Li<sub>2</sub>HfTeO<sub>6</sub>, W for Mn<sub>2</sub>FeWO<sub>6</sub> and Mn<sub>3</sub>WO<sub>6</sub>, and Os for Zn<sub>2</sub>FeOsO<sub>6</sub>. These results are consistent with the analysis of  $\xi_{1S}$  and  $\xi_{2S}$ , as shown in Table V. We find that the energy difference between the two distinct midpoint structures is mainly due to the difference  $\Delta E^{M} = E_{B'}^{M} - E_{B'}^{M}$  between the Madelung energies of the two structures in a simple point-ion model, as shown in Table. V.
